

## ABSTRACT

The present invention relates to a web processing device, comprising a plurality of pads  $P_i$  revolving around a axis  $X1$ , a cutter 30 for cutting a continuous web  $W$ , and a plurality of anvils  $A_i$  for receiving the cutter 30. The pads  $P_i$  receive the continuous web  $W$ , and the cutter 30 cuts the continuous web  $W$  into a cut-off web  $W2$  together with the anvil  $A_i$  positioned at a first relative level  $L1$ . The pad  $P_i$  revolves around the axis  $X1$  while changing an attitude of the pad  $P_i$  by turning about a line extending from the first axis toward the pad  $P_i$ , thereby carrying the cut-off web  $W2$  while changing an attitude of the cut-off web  $W2$ . When the pad  $P_i$  changes its attitude, the anvil  $A_i$  relatively moves to a second relative level  $L2$  so as not to hinder the pad  $P_i$  changing its attitude.
